

Increasing Military Patient Use of Secure Messaging

Provider encouragement and on-the-spot assistance increased patient registrations for secure messaging

Agency Objective Increase the rate at which patients register for and use secure messaging to communicate with their healthcare providers.

Background The US Military Health System (MHS) provides secure online messaging to allow patients to send questions to their providers, get lab results, and renew prescriptions. However, only 47% of enrollees are registered, and only 6% utilize the portal, as of April 2017 – leaving about 1.8 million patients who do not currently have access to use this benefit.¹ Research suggests that individuals may not enroll because of lack of information, lack of motivation, and negative attitudes toward the portal.^{2,3}

Program Change The Office of Evaluation Sciences (OES) collaborated with the Defense Health Agency's (DHA) Patient Centered Medical Home (PCMH) Office and the Family Medicine Clinic at Naval Hospital Camp Lejeune (NHCL) to design an intervention added to family medicine appointments. The intervention consisted of providers making a personal appeal to register in the secure messaging system during a patient's visit, on-site staff assistance in signing patients up, and staff providing a checkout sheet to patients with instructions for registering later.⁴

Evaluation Methods Providers and staff at the

NHCL Family Medicine Clinic implemented the intervention for six and half months, from mid-July 2016 through January 2017. OES, in collaboration with DHA and NHCL, evaluated the impact of this intervention by comparing patient registration for secure messaging at the NHCL Family Medicine Clinic with family medicine clinics at seven other demographically similar military treatment facilities (MTFs) selected by DHA.

Results At the NHCL Family Medicine Clinic, the number of patients registered for secure messaging rose by 15.0% between the month prior and the final month of the trial. By contrast, at the seven comparison sites, the average number of patients registered for secure messaging rose just 3.0%. We estimate that the intervention was associated with an additional 224 patients registering in the secure messaging system per month ($p < .001$, 95% CI = [188, 260]), compared to a background growth in registrations of 48 per month across all of the sites. This constituted a greater than five-fold increase in the rate at which registrations grew.

⁴ Patients of roughly half of the providers also received a follow-up email about registering for secure messaging – a secondary intervention that we will report on separately.

Increasing Military Patient Use of Secure Messaging

Provider encouragement and on-the-spot assistance increased patient registrations for secure messaging

Conclusion For more than half of MHS beneficiaries, the benefits of registering for secure messaging to communicate with providers and staff remain untapped. A simple intervention involving provider encouragement and staff assistance was associated with a large increase in the rate at which patients registered for this benefit – a result that suggests the potential for similar interventions in other clinics and at other treatment facilities across the MHS.
